#### Abstract

Due to a large-scale problem, solving unconstrained optimization using classical Newton's method is typically expensive to store its Hessian matrix and solve its Newton direction. Therefore, in this paper, we proposed a NewtonMSOR method for solving large scale unconstrained optimization problems whose Hessian matrix is an arrowhead matrix to overcome these problems. This Newton-MSOR method is a combination of the Newton method and modified successive-over relaxation (MSOR) iterative method. Some test functions are provided to show the validity and applicability of the proposed method. In order to calculate the performance of the proposed method, combinations between the Newton method with Gauss-Seidel point iterative method and the Newton method with successive-over relaxation (SOR) point iterative method were used as reference methods. Finally, the numerical results show that our proposed method provides results that are more efficient compared to the reference methods in terms of execution time and a number of iterations.

KEYWORDS: Newton method; MSOR iteration; Unconstrained optimization problems; Large-scale optimization; Iterative solution of linear systems; Arrowhead matrix.

## INTRODUCTION

In this paper we only interested in large-scale problems ( $n \geq 1000$ ), therefore we study a largescale unconstrained optimization problem which specified as

$$
\begin{equation*}
\min _{\underline{\mathbf{x}} \in \mathfrak{R}^{n}} f(\underline{\mathbf{x}}) \tag{1}
\end{equation*}
$$

where $f: \mathfrak{R}^{n} \rightarrow \mathfrak{R}$ is twice continuously differentiable. Generally, problem (1) can be solved using various type of method such as stated in Sun \& Yuan (2006). Through the list of techniques discussed by them, we are more attracted to Newton's method. Since Newton's method possesses a fast quadratic rate of convergence, and it is also known as the best-known method on its outstanding performance when the starting point is choosing appropriately (Nocedal \& Wright, 2000). Despite these reasons, notice that Newton's method has disadvantages when the problem is in the largescale which is lead to difficulties in finding its second derivatives. Therefore many researchers have modified Newton's method to overcome the disadvantages such as proposed by Kaniel \& Dax (1979), Shi (2000), Grapsa (2014) and Dehghan Niri et al. (2018).

Kaniel \& Dax (1979) proposed a modified Newton's method for unconstrained minimization through the use of the symmetric decomposition as an alternative method for searching the Newton direction in solving the classical Newton method, while Shi (2000) combining the Newton direction with the steepest descent direction to achieve global and high local convergence order. Also, Grapsa (2014) proposed a new class of modified Newton's direction methods using a proper gradient's vector modification to have an efficient quadratic model with a new direction for solving problems of unconstrained optimization. Dehghan Niri et al. (2018) proposed a modified regularized Newton method for solving unconstrained optimization problems whose Hessian matrix may be singular without line search and analyze its convergence.

Thus, in this paper, we proposed an alternative method for finding large-scale unconstrained optimization problems with an arrowhead Hessian matrix by combining the Newton method with MSOR point iterative method, namely as Newton-MSOR method. This combination uses the MSOR iterative method for finding the Newton direction, while Newton's method is used to estimate the solution of problem (1). Kincaid and Young (1972) who are responsible for introducing the MSOR iterative method using two different relaxation factors to produce the fastest convergence which categorized as one of the numerical techniques that have an advantage of the efficient point iteration for solving any linear systems including large-scale system. To analyze the performance of our proposed method, we consider a combination of Newton method with SOR iteration and Newton method with Gauss-Seidel iteration as reference methods and they are called as Newton-SOR method and Newton-GS method respectively.

## NEWTON SCHEME WITH AN ARROWHEAD HESSIAN MATRIX

In this paper, we start by using the quadratic Taylor approximation to $\underline{f}(\underline{\mathbf{x}})$ around the current point $\underline{\mathbf{x}}^{(k)}$, and then we minimize this approximation to have the next point $\underline{\mathbf{x}}^{(k+1)}$. Therefore we replace problem (1) as

$$
\begin{equation*}
\min _{\underline{\mathbf{x}} \in \Re^{n}} f\left(\underline{\mathbf{x}}^{(k)}\right)+\left[\nabla \underline{f}\left(\underline{\mathbf{x}}^{(k)}\right)\right]^{T}\left(\underline{\mathbf{x}}-\underline{\mathbf{x}}^{(k)}\right)+\frac{1}{2}\left(\underline{\mathbf{x}}-\underline{\mathbf{x}}^{(k)}\right)^{T} \nabla^{2} \underline{f}\left(\underline{\mathbf{x}}^{(k)}\right)\left(\underline{\mathbf{x}}-\underline{\mathbf{x}}^{(k)}\right) . \tag{2}
\end{equation*}
$$

To solve problem (2), we set the gradient of this approximation to zero, so that we can have

$$
\begin{equation*}
\nabla \underline{f}\left(\underline{\mathbf{x}}^{(k)}\right)+\mathbf{H}\left(\underline{\mathbf{x}}^{(k)}\right)\left(\underline{\mathbf{x}}^{(k+1)}-\underline{\mathbf{x}}^{(k)}\right)=0 \tag{3}
\end{equation*}
$$

where $\mathbf{H}\left(\underline{\mathbf{x}}^{(k)}\right)=\nabla^{2} \underline{f}\left(\underline{\mathbf{x}}^{(k)}\right)$ as the Hessian matrix of second partial derivatives of $\underline{f}(\underline{\mathbf{x}})$. By simplifying equation (3), we can obtain the Newton iteration;

$$
\begin{equation*}
\underline{\mathbf{x}}^{(k+1)}=\underline{\mathbf{x}}^{(k)}-\left[\mathbf{H}\left(\underline{\mathbf{x}}^{(k)}\right)\right]^{-1} \nabla \underline{f}\left(\underline{\mathbf{x}}^{(k)}\right) \tag{4}
\end{equation*}
$$

with its Newton direction;

$$
\begin{equation*}
\underline{d}^{(k)}=-\left[\mathbf{H}\left(\underline{\mathbf{x}}^{(k)}\right)\right]^{-1} \nabla \underline{f}^{\left(\underline{\mathbf{x}}^{(k)}\right) .} \tag{5}
\end{equation*}
$$

As a particularly interesting case, we only considered Hessian of an arrowhead matrix of order $n$ with the general form given by Stanimirovic et al. (2019);

$$
\mathbf{H}\left(\underline{\mathbf{x}}^{(k)}\right)=\left[\begin{array}{ccccc}
\frac{\partial^{2} f}{\partial x_{1}^{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{3}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{n-1}} \\
\frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{2}^{2}} & 0 & \cdots & 0 \\
\frac{\partial^{2} f}{\partial x_{3} \partial x_{1}} & 0 & \frac{\partial^{2} f}{\partial x_{3}^{2}} & \ddots & \vdots \\
\vdots & \vdots & \ddots & \ddots & 0 \\
\frac{\partial^{2} f}{\partial x_{n} \partial x_{1}} & 0 & \cdots & 0 & \frac{\partial^{2} f}{\partial x_{n}^{2}}
\end{array}\right] .
$$

## FORMULATION OF THE PROPOSED ITERATIVE METHOD

Since the Hessian of an arrowhead matrix, $\mathbf{H}\left(\underline{x}^{(k)}\right)$ is large and sparse, therefore finding the inverse of $\mathbf{H}\left(\underline{x}^{(k)}\right)$ by using direct method can cause a great computational cost that will lead to a solution involving very tedious work. As another solution, we used an iterative method as in Young (1971) and Youssef and Taha (2013) for solving a large linear system of equation (5). Let the linear system (5) Error! Reference source not found.be rewritten in general form as

$$
\begin{equation*}
\mathbf{A} \underline{d}=\underline{f} \tag{6}
\end{equation*}
$$

where,

$$
\mathbf{A}=\left[\begin{array}{ccccc}
b_{1} & c_{1} & c_{2} & \cdots & c_{n-1} \\
a_{2} & b_{2} & 0 & \cdots & 0 \\
a_{3} & 0 & b_{3} & \ddots & \vdots \\
\vdots & \vdots & \ddots & \ddots & 0 \\
a_{n} & 0 & \cdots & 0 & b_{n}
\end{array}\right], \underline{d}=\left[\begin{array}{c}
d_{1} \\
d_{2} \\
d_{3} \\
\vdots \\
d_{n}
\end{array}\right], \underline{f}=\left[\begin{array}{c}
f_{1} \\
f_{2} \\
f_{3} \\
\vdots \\
f_{n}
\end{array}\right] .
$$

with $b_{1}, b_{2} \ldots, b_{n}, a_{2}, \ldots, a_{n}, c_{1}, c_{2} \ldots, c_{n-1} \in \mathfrak{R}$. To develop the formulation of our proposed iterative method, we decomposed the real coefficient matrix $\mathbf{A}$ of the linear system (6) as;

$$
\begin{equation*}
\mathbf{A}=\mathbf{D}-\mathbf{L}-\mathbf{U} \tag{7}
\end{equation*}
$$

where $\mathbf{D}$ is the nonzero diagonal part, $\mathbf{L}$ is strictly lower triangular part and $\mathbf{U}$ is strictly upper part, of $\mathbf{A}$. By applying the decomposition in equation (7) into linear system (6) and considering the implementation of two different relaxation parameters, the iterative formulation of the MSOR method can be stated in vector form as (Kincaid \& Young, 1972);

$$
\begin{align*}
& \underline{d}_{i+1}{ }^{(k+1)}=\left(\mathbf{D}-\omega_{1} \mathbf{L}\right)^{-1}\left(\omega_{1} \mathbf{U}+\left(1-\omega_{1}\right) \mathbf{D}\right) \underline{d}_{i}^{(k)}+\omega_{1}\left(\mathbf{D}-\omega_{1} \mathbf{L}\right)^{-1} \underline{f}_{i}, \quad i=1,3, \ldots, n-1 \\
& \underline{d}_{i+1}{ }^{(k+1)}=\left(\mathbf{D}-\omega_{2} \mathbf{L}\right)^{-1}\left(\omega_{2} \mathbf{U}+\left(1-\omega_{2}\right) \mathbf{D}\right) \underline{d}_{i}^{(k)}+\omega_{2}\left(\mathbf{D}-\omega_{2} \mathbf{L}\right)^{-1} \underline{f}_{i}, \quad i=2,4, \ldots, n \tag{8}
\end{align*}
$$

where $\omega_{1}$ and $\omega_{2}$ represent as a relaxation parameter with the optimal value in the range of $[1,2$ ) and selected based on the smallest number of inner iterations. For the implementation of point iterations, each component $d_{i}^{(k+1)}$ can be computed as;

$$
\begin{gather*}
d_{i}^{(k+1)}=\left(1-\omega_{1}\right) d_{i-1}^{(k)}+\frac{\omega_{1}}{b_{i}}\left(f_{i}-\sum_{1}^{n-1} c_{j} d_{i+1}^{(k)}\right), \text { for } i=1 \\
d_{i}^{(k+1)}=\left(1-\omega_{1}\right) d_{i-1}^{(k)}+\frac{\omega_{1}}{b_{i}}\left(f_{i}-a_{i} d_{1}^{(k)}\right), \text { for } i=3,5, \ldots, n-1  \tag{9}\\
d_{i}^{(k+1)}=\left(1-\omega_{2}\right) d_{i-1}^{(k)}+\frac{\omega_{2}}{b_{i}}\left(f_{i}-a_{i} d_{1}^{(k)}\right), \text { for } i=2,4, \ldots, n
\end{gather*}
$$

By using the formulation of the MSOR iterative method to calculate the Newton direction (4) in Newton equation (5), we proposed the algorithm of Newton-MSOR scheme for solving problem (1). Note that for $\omega_{1}=\omega_{2}=1$ equation (9) is reduced to the GS method and if $\omega_{1}=\omega_{2} \equiv \omega$, then equation (9) is reduced to the SOR method. Therefore, by using equation (6) and (9), we propose the reliable algorithm of Newton-MSOR scheme with an arrowhead Hessian matrix for solving problem (1) and stated it in Algorithm 1.

```
Algorithm 1: Newton-MSOR with an Arrowhead Hessian Matrix Scheme
    i. Initialize
            Set up the objective function: \(f(\underline{x}), \underline{x}^{(0)} \leftarrow \mathfrak{R}^{n}, \varepsilon_{1} \leftarrow 10^{-6}, \varepsilon_{2} \leftarrow 10^{-8}\) and \(n \leftarrow \mathfrak{R}\)
ii. Assign the optimal value of \(\omega_{1}\) and \(\omega_{2}\)
iii. For \(j=1,2, \ldots, n\) implement
    a. Set \(\underline{d}^{(0)} \leftarrow 0\)
    b. Calculate \(f\left(\underline{x}^{(k)}\right)\)
    c. Calculate the approximate value of \(d_{i}^{(k+1)}\) by solve equation (6) using equation (9)
    d. Check the convergence test, \(\left\|\underline{d}^{(k+1)}-\underline{d}^{(k)}\right\| \leq \varepsilon_{2}\). If yes, go to step (e). Otherwise, go back to step (b)
    e. For \(i=1,2, \ldots, n\) calculate; \(\underline{x}^{(k+1)} \leftarrow \underline{x}^{(k)}+\underline{d}^{(k)}\)
    f. Check the convergence test, \(\left\|\nabla \underline{f}\left(\underline{x}^{(k)}\right)\right\| \leq \varepsilon_{1}\). If yes, go to (iii). Otherwise, go back to step (a)
```

iv. Display approximate solutions

## NUMERICAL EXPERIMENTS AND COMPUTATIONAL RESULTS

To check the performance of the proposed Algorithm, we have run the numerical experiments using three artificial problems obtained from the collection collected by Andrei (2004; 2008) where all of these problems have the same characteristic of Hessian that is an arrowhead Hessian matrix. The details for each of the three test functions are stated in Table 1. For each of these test functions, we use three different initial points. One of them is as suggested in Andrei (2004; 2008), and we labeled it as a standard initial point while the other two initial points are chosen randomly from a range surrounding the standard initial point or the optimal point. We specify it as a nonstandard initial point 1 and nonstandard initial point 2 in Table 1. Therefore in total, we have nine test cases which can be defined by test number. For example, we indicate the test case defined by test number 1 with a nonstandard initial point 2 as $1(\mathrm{~b})$.

Table 1. Specifications of the test functions.

| Test <br> Number | Test Name, Algebraic Expression, local optimal value and optimal point | Initial point, $\mathbf{x}^{(0)}$ |  |
| :---: | :---: | :---: | :---: |
|  |  | (a) Standard | (b) Nonstandard 1 <br> (c) Nonstandard 2 |
| 1 | LIARWHD $\begin{aligned} & f(\underline{\mathrm{x}})=\sum_{i=1}^{n} 4\left(x_{i}^{2}-x_{1}\right)^{2}+\left(x_{i}-1\right)^{2} \\ & f^{*}=0 \text { and } \mathbf{x}^{*}=(1.0,1.0, \ldots, 1.0) \end{aligned}$ | (4.0,4.0,..., 4.0) | $\begin{gathered} (1.5,1.5, \ldots, 1.5) \\ (3.3,3.5, \ldots, 3.3,3.5) \end{gathered}$ |
| 2 | NONDIA $\begin{aligned} & f(\underline{\mathrm{x}})=\left(x_{1}-1\right)^{2}+\sum_{i=2}^{n} 100\left(x_{i}-x_{i-1}^{2}\right)^{2} \\ & f^{*}=0 \text { and } \mathbf{x}^{*}=(1.0,1.0, \ldots, 1.0) \end{aligned}$ | $(-1.0,-1.0, \ldots,-1.0)$ | $\begin{gathered} (2.0,2.0, \ldots, 2.0) \\ (2.0,1.5, \ldots, 2.0,1.5) \end{gathered}$ |
| 3 | DIAG-AUP1 $\begin{aligned} & f(\underline{\mathrm{x}})=\sum_{i=1}^{n} 4\left(x_{i}^{2}-x_{1}\right)^{2}+\left(x_{i}^{2}-1\right)^{2} \\ & f^{*}=0 \text { and } \mathbf{x}^{*}=(1.0,1.0, \ldots, 1.0) \end{aligned}$ | (4.0, 4.0, ..., 4.0) | $\begin{gathered} (1.5,1.5, \ldots ., 1.5) \\ (3.3,3.5, \ldots, 3.3,3.5) \end{gathered}$ |

The computational result of the proposed and references method was compiled using C language with double precision arithmetic. For each test cases, we performed five numerical experiments with a different order of Hessian matrix as $n=\{1000,5000,10000,20000,30000\}$. We report the computational result of the Newton-GS (Ngs), Newton-SOR (Nsor), and Newton-MSOR (Nmsor) in Table 2. The detailed numerical results, including the number of inner iteration ( $\mathrm{NI}_{\mathrm{i}}$ ), the number of outer iteration $\left(\mathrm{NI}_{0}\right)$, the execution time in seconds $(t)$, function value at the iterate where execution terminated $\left(\mathrm{FV}_{t}\right)$ and maximum error $\left(\mathrm{Max}_{\varepsilon}\right)$. All values tabulated in Table 2 are rounded up to two decimal places. Therefore, all maximum error values are smaller than the convergence tolerance, $\varepsilon_{2}$. Finally, to have well understood for the efficiency of the comparison results in term of the execution time, we have computed the comparison of speedup ratio for Newton-MSOR method with both the reference methods in Table 3. In this table, we used the total execution time in seconds $\left(\Sigma_{t}\right)$ for every test cases.

## CONCLUSION

Base on all the results given in the previous section, we can conclude that in the process for solving large-scale unconstrained optimization problems with an arrowhead Hessian matrix, our proposed algorithm is efficient compared to the reference methods. This comparison has shown through the execution time and the number of iterations given in Table 2. For the accuracy, we can observe through all value indicates as the approximate value under column $\mathrm{FV}_{t}$ and it is shown that
they are very approaching the optimal value except seven values obtained from the references method (in the test case 1(c)) and not from the proposed method. Therefore, the selection of an excellent initial point can influence the efficiency of the initial search process. As expected, with the use of the relaxation factor, the speedup ratio for Newton-MSOR and Newton-SOR were much faster than Newton-GS. From the speedup ratio in Table 3, we see that Newton-MSOR is up to 1.93 times faster than Newton-SOR and up to 358.18 times more rapid than Newton-GS. Thus, it can be concluded that our proposed iterative method (Newton-MSOR) can show substantial improvement in the number of iterations and execution time compared to the Newton-SOR and Newton-GS point iterative methods. In the future, we will investigate the efficiency of the combination of the Newton method with block iterative approach as in Ghazali et al. $(2018,2019)$ and Sulaiman et al. $(2012)$.
